3637 Westwind Blvd
Santa Rosa, CA 95403
${ }^{2 /}$ Pacific States Marine Fisheries Commission

This report is funded by the U.S. Bureau of Reclamation, East Bay Municipal Utilities District, and the California Department of Water Resources contracts with the Pacific States Marine Fisheries Commission (PSMFC). The work necessary to produce this report was a cooperative effort between the California Department of Fish and Wildlife and the PSMFC. For a copy of this report, please contact Pete McHugh at Peter.McHugh@wildlife.ca.gov.

## INTRODUCTION

Each year, approximately 32 million fall-run Chinook salmon (Oncorhynchus tshawytscha) are produced at five hatcheries in California's Central Valley (CV): Coleman National Fish Hatchery (CFH), Feather River Hatchery (FRH), Nimbus Fish Hatchery (NIM), Mokelumne River Hatchery (MOK), and Merced River Hatchery (MER). Production from these hatcheries contributes to CV escapement and sport harvest while also supporting ocean fisheries in California and Oregon. Since 2007, a constant fractional marking (CFM) program has ensured that at least $25 \%$ of all CV hatchery production fish are tagged with a microscopic ( $\leq 1 \mathrm{~mm}$ ) coded-wire tag (CWT). Each CWT contains a binary or alpha-numeric code that identifies a specific release group of salmon (e.g., agency, species, run, brood year, hatchery or wild stock, release size, release date(s), release location(s), number tagged and untagged). Each salmon containing a CWT is also externally marked with a clipped adipose fin (ad-clip) to allow for easy visual identification.

This is the tenth annual report on the recovery of CFM CWTs in the CV and ocean fisheries. In 2019, approximately 56,500 CWTs were recovered and successfully read from ad-clipped Chinook salmon sampled in CV fall-, winter-, spring-, and late-fall-run natural area spawning surveys, at CV hatcheries, in the CV angler sport harvest, and in commercial and sport ocean salmon fisheries south of Cape Falcon (i.e., California and most of Oregon).

This report will focus primarily on the results of analyses addressing the following questions:

- What are the proportions of hatchery- and natural-origin salmon in spawner returns to CV hatcheries and natural areas, in inland harvest, and in ocean fisheries? Of the hatchery component, what proportions originated from in-basin versus out-of-basin CWT release strategies?
- What are the relative recovery and stray rates for hatchery-origin salmon released in-basin versus salmon released into the waters of the Sacramento-San Joaquin River Delta, San Francisco-San Pablo bays, or coastal areas? How do recovery and stray rates differ between salmon acclimated in net pens and their siblings released directly into the water? Are these metrics affected by transporting salmon smolts down their natal waterways by vessel and exposing them to river water prior to release in the bay?
- What are the relative recovery and contribution rates of hatchery-origin salmon, by run and release type, to ocean and inland harvests?

Please see earlier CFM reports (Kormos et al. 2012, Palmer and Kormos 2013, 2015) for more information and discussion regarding the CFM program, CWT recovery programs, and the methods and analyses used in this report. Additional information on salmon escapement monitoring can be found in the Central Valley Chinook Salmon Escapement Monitoring Plan (Bergman et al. 2012) and other CV salmon population reports (e.g., FWS 2020, Kelly and Phillips 2020, Kowalik and Massa 2020).

## DATA AND METHODS

## Inland Escapement and River Sport Harvest Monitoring

During 2019, monitoring of salmon escapement occurred at all five salmon hatcheries and on major rivers and tributaries throughout the CV. In addition, an angler creel survey was conducted on sport fisheries in the Sacramento, Feather, American, and Mokelumne river basins. It should be noted that the late-fall-run escapement in the upper Sacramento River and at CFH in this report is considered the 2020 return year, however the escapement monitoring period began in late 2019.

Sampling and estimation methods (e.g., carcass surveys, snorkel surveys, weir counts) continue to vary among natural spawner surveys throughout the CV (Table 1); however, most 2019 surveys on major rivers and in the hatcheries adequately sampled (sample rate $\geq 20 \%$ ) for ad-clipped fish. The sampling rate was generally lower for smaller creeks where biodata was collected over a few days or in limited areas.

Of the approximately 271,100 Chinook salmon that returned to the CV basins analyzed in this report, 114,000 salmon were sampled, 32,600 ad-clipped salmon were observed, and 31,100 heads were collected by various CV projects. Monitoring agencies and projects included the California Department of Fish and Wildlife (CDFW), California Department of Water Resources (DWR), East Bay Municipal Utility District (EBMUD), Pacific States Marine Fisheries Commission (PSMFC), U.S. Bureau of Reclamation, U.S. Fish and Wildlife Service (FWS), and the Yuba Accord River Management Team (YARMT). Most inland heads were processed by CDFW at the Sacramento CWT lab, except for 7,100 heads processed by FWS staff at CFH, 200 heads processed by FWS staff in Lodi, and 1,200 heads processed by CDFW staff in Red Bluff.

All estimates of CV escapement or harvest and the number of salmon sampled in this report were provided by individual monitoring projects or hatcheries.

## Ocean Harvest Monitoring

In 2019, California sport and commercial ocean salmon fisheries (Table 2) had increased opportunities compared to the two years prior due to improved abundance forecasts for fall-run Chinook salmon from the Sacramento and Klamath basins. Of the approximately 359,900 salmon harvested in California ocean fisheries during 2019, CDFW field staff sampled 111,600 salmon and collected 20,700 heads that were processed at the Santa Rosa CWT lab. Almost 1,800 heads collected in Oregon sport and commercial ocean fisheries during 2019 are also included in these analyses since Sacramento River fall-run Chinook salmon is the primary stock harvested in fisheries south of Cape Falcon, Oregon (PFMC 2016).

Each year, CDFW validates and uploads all CWT recoveries in California, along with their respective catch-sample data, to the Regional Mark Processing Center (RMPC), which is the central repository for west coast CWT recoveries. All 2019 inland and ocean CWT recoveries are publicly available on the RMPC website at www.rmpc.org.

## CWT Data Analysis

A master release database of CWT codes recovered in 2019 was created to determine species, brood year, run, stock origin (hatchery or natural), release site, release date(s), number of salmon tagged with CWTs, total number of salmon released, and any other pertinent release information (e.g., trucked, net pen acclimation, disease issues). Since almost all CV salmon recovered are between the ages of two and five, all CWT release data for Chinook salmon brood years 2014 through 2017 were downloaded from the RMPC. Approximately 127 million CV salmon were released for these brood years, of which 45 million were marked and tagged utilizing 390 unique CWT codes. Although a few thousand natural-origin salmon are often trapped, marked, and tagged annually, salmon produced by hatcheries make up 99\% or greater of all CWT releases. In 2019, there were 250 individual CWT codes recovered in the CV, primarily from age-2, age-3, and age-4 salmon. The CWT master file was updated with any additional information obtained for special CV salmon releases (e.g., barge study) and the production factor calculated for each CWT code. The production factor, $F_{\text {prod, }}$ is the ratio of the total number of salmon released to the total number of salmon marked containing a CWT. Thus, it is the total number of salmon (i.e., tagged and untagged) represented by each CWT recovery. Fprod was calculated for each CWT code and is defined as,

$$
F_{\text {prod }}=(\text { Ad.CWT + Ad.noCWT + noAd.CWT + noAd.noCWT) / Ad.CWT, }
$$

where Ad.CWT is the number of salmon released with ad-clips and CWTs, Ad.noCWT is the number of salmon released with ad-clips but without CWTs (i.e., shed tags prior to release or CWT not correctly inserted), noAd.CWT is the number of salmon released without ad-clips but with CWTs, and noAd.noCWT is the number of salmon released without ad-clips and without CWTs. $F_{\text {prod }}$ allows expansion to total hatchery production from observed recoveries of CV CWTs. It should be noted that certain release types (e.g., barge study) experienced significant pre-release mortality due to factors related to transport and predation at the release site that went unreported in the RMPC. In some cases, where numbers of mortalities are unavailable in the release information, the resulting calculation for $F_{\text {prod }}$ may bias results.

For this analysis, each CV Chinook salmon CWT release was classified into a "release type" based on the following criteria: hatchery or natural stock, run, release location, and release strategy. All CV CWT codes were assigned by brood year into one of fifteen fall-run, two winter-run, two spring-run, or one late-fall-run release types:

Sacramento River Basin Fall-run Chinook salmon release types
CFHF Coleman National Fish Hatchery Fall-run in-basin releases
CFHFn Coleman National Fish Hatchery Fall-run bay/delta net pen releases
FRHF Feather River Hatchery Fall-run in-basin releases
FRHFn Feather River Hatchery Fall-run bay/delta net pen releases
FRHFgg Feather River Hatchery Fall-run Golden Gate releases (no net pen acclimation)
NIMF Nimbus Fish Hatchery Fall-run in-basin releases
NIMFn Nimbus Fish Hatchery Fall-run bay/delta net pen releases

San Joaquin River Basin Fall-run Chinook salmon release types
MOKF Mokelumne River Hatchery Fall-run in-basin releases
MOKFn Mokelumne River Hatchery Fall-run bay/delta net pen releases
MOKFnc Mokelumne River Hatchery Fall-run coastal net pen releases (Pillar Point/Santa Cruz)
MOKFgg Mokelumne River Hatchery Fall-run Golden Gate releases (no net pen acclimation)
MOKFb Mokelumne River Hatchery Fall-run barge study releases
MERF Merced River Hatchery Fall-run in-basin releases
MERFn Merced River Hatchery Fall-run bay/delta net pen releases
MERFt Merced River Hatchery Fall-run trucked releases (no net pen acclimation)
Sacramento River Winter-run Chinook salmon release types
SacW Sacramento River Winter-run supplementation natural production releases (in-basin)
SacWbat Sacramento River Winter-run Battle Creek reintroduction releases (in-basin)

Central Valley Spring-run Chinook salmon release types
FRHS Feather River Hatchery Spring-run in-basin releases
SJOSx San Joaquin River Spring-run experimental reintroduction releases (in-basin)

Central Valley Late-fall-run Chinook salmon release types
CFHL Coleman National Fish Hatchery Late-fall-run in-basin releases

Note that not all release types occur every year and that release sites sometimes vary within a given release type (Table 3; Fig. 1). There were also a few problematic CWT releases where fish were released utilizing more than one strategy (e.g., one out of the fifteen bay/delta net pen MOKFn release groups from the 2017 brood was not actually acclimated in net pens due to traffic delays). Thus, we urge caution when analyzing or comparing CWT recovery data from certain release types. Releases that were part of the Knaggs Ranch rice field study have been excluded from this report, as there was only one inland recovery (an age-4 fish released as part of an in-river control group) and no ocean recoveries in 2019.

To estimate the total escapement or harvest associated with each CWT recovery, each tag recovery was expanded by its respective $F_{\text {prod }}$ and sample expansion factor, $F_{\text {samp }}$, which is defined as,

$$
F_{\text {samp }}=1 /\left(f_{e} \times f_{a} \times f_{d}\right),
$$

where $f_{e}$ is the fraction of the total salmon escapement or harvest sampled and visually examined for an ad-clip, $f_{a}$ is the fraction of heads from ad-clipped salmon collected and processed, and $f_{d}$ is the fraction of observed CWTs that were successfully decoded (Tables 4 and 5).

Salmon sampled in CV carcass surveys are generally classified as 'fresh' or 'non-fresh' based on criteria such as condition of the eyes (clear vs. opaque) or gills (pink vs. grey). Often the ad-clipped (marked) status of a non-fresh (i.e., decayed) salmon cannot be
determined due to the deteriorating condition of the carcass. While condition criteria are somewhat ambiguous and classification may vary among surveys, the ad-clip rate of fresh salmon sampled in 2019 was generally higher or similar to the rate observed in non-fresh fish (Appendix 1). Fresh carcass heads also usually contain CWTs at a higher rate than heads collected from non-fresh fish, although that was not the case for most surveys in 2019. Furthermore, the sample sizes between fresh and non-fresh fish are usually very different with the number of non-fresh salmon sampled generally much greater than fresh salmon in surveys that collected both conditions.

Mohr and Satterthwaite (2013) demonstrated how the sampling differences noted above could negatively bias the estimates of hatchery contribution. However, they cautioned that using only CWT data from fresh fish could eliminate the occurrence of rare CWT codes in analyses due to the small sample sizes common with fresh carcasses in these surveys. As in previous CFM reports, the following equation developed by Mohr and Satterthwaite (2013) was used to calculate $F_{\text {samp }}$ for carcass surveys collecting fish condition data, thus reducing the potential to underestimate hatchery contribution while still incorporating CWT codes from both fresh and non-fresh fish:

$$
F_{\text {samp }}=\left(N \times p \_a d c\left|f r e s h \times p \_c w t\right| f r e s h, a d c\right) /\left(\eta_{\text {valid } c w t}\right)
$$

where $N=$ estimated total escapement, $p_{-}$adc|fresh = proportion of fresh salmon sampled that were ad-clipped, $p_{-} c w t \mid f r e s h, a d c=$ proportion of ad-clipped fresh salmon that contained a CWT, and $n_{\text {valid cwt }}=$ total number of valid CWTs collected from fresh and decayed salmon.

To help differentiate between raw CWT recoveries, CWT recoveries expanded for production, CWTs expanded for sampling, and CWTs expanded for production and sampling, the following nomenclature is used:

| $C W T$ | $=$ Raw count $C W T$ recoveries |
| :--- | :--- |
| $C W T_{\text {prod }}$ | $=$ CWT recoveries expanded by their respective production factor, $F_{\text {prod }}$ |
| $C W T_{\text {samp }}$ | $=$ CWT recoveries expanded by their respective sample expansion factor, $F_{\text {samp }}$ |
| $C W T_{\text {total }}$ | $=$ CWT recoveries expanded by both $F_{\text {prod }}$ and $F_{\text {samp }}$ |

## Determining hatchery- and natural-origin proportions in CV escapement and harvest

To determine the contribution of hatchery- and natural-origin salmon, all $C W T_{\text {total }}$ were summed to estimate the total number of hatchery salmon in each survey. The contribution of natural-origin salmon for each survey was then determined by subtracting the total number of hatchery salmon from the total escapement estimate, as follows:

$$
\text { Estimate of natural-origin salmon }=\text { Total escapement estimate }-\sum_{i=1}^{m} C W T_{\text {total }, i},
$$

where $m=$ total number of hatchery-origin CWT release groups identified in an escapement survey or hatchery.

## Determining recovery rates of various release types in CV escapement and ocean harvest

To determine the relative CV recovery rate, $R_{\text {cwt }}$, of each unique CWT release group (i.e., code), all recoveries were expanded by their location-specific $F_{\text {samp }}$, summed over all recovery locations, and then divided by the total number of salmon tagged and released with this CWT. Since expanded recoveries for several individual CWT groups were less than $0.001 \%$ of the total number released, recovery rates are reported in recoveries per 100,000 CWT salmon released, as follows:

$$
R_{\text {cwt }}=\sum_{j=1}^{l} C W T_{\text {samp.j }} \text { recoveries / (CWT release group size / 100,000) },
$$

where $j(=1,2,3, \ldots, l)$ denotes recovery location.
Data from all CWT release groups belonging to the same brood year and release type (e.g., coastal net pen) were combined and an overall release type-specific CV recovery rate, $R_{\text {type }}$, was calculated as:

$$
R_{\text {type }}=\sum_{j=1}^{l} \sum_{k=1}^{n} C W T_{\text {samp }, j, k} /\left(\sum_{k=1}^{n} \text { release group size of } C W T_{k} / 100,000\right)
$$

where $k(=1,2,3, \ldots, n)$ denotes release group.

## Determining stray proportions of various release groups in CV escapement

To be consistent with previous reports (Kormos et al. 2012, Letvin et al. 2020, 2021, Palmer-Zwahlen and Kormos 2013, 2015, 2020, Palmer-Zwahlen et al. 2018, 2019a, 2019b), basin-of-origin is defined as the drainage within which a particular hatchery is located. Given the five hatcheries under consideration in this report, the CV is divided into five hatchery basins (hatchery code in parentheses): (1) upper Sacramento River,
including Battle Creek (CFH), (2) Feather River, including the Yuba River (FRH), (3) American River (NIM), (4) Mokelumne River (MOK), and (5) Merced River (MER). Hatchery-origin salmon not returning to their basin-of-origin or to streams and rivers not included in any hatchery basin (e.g., Butte Creek, Stanislaus River, Tuolumne River) are considered strays. Appendices 2 and 3 present alternative recovery and stray rates for CFH and FRH CWT releases based on the assumption that recoveries in the upper Sacramento River and Yuba River, respectively, are strays.

To determine the CV stray proportion, $S_{\text {cwt }}$, for each CWT code, the sum of all $C W T_{\text {samp }}$ recoveries collected outside the basin of origin was divided by total CV $C W T_{\text {samp }}$ recoveries for that release group, as follows:

$$
S_{\mathrm{cwt}}=\sum_{p=1}^{o} C W T_{\text {samp.p }} \text { (out-of-basin locations) } / \sum_{p=1}^{q} C W T_{\text {samp }, p} \text { (all CV locations), }
$$

where $p$ denotes recovery location, o denotes the number of out-of-basin recovery locations, and $q$ denotes the total number of recovery locations.

Data from all CWT releases belonging to the same brood year and release type were combined and release type-specific CV stray proportion, $S_{\text {type, }}$ was calculated as:

$$
S_{\text {type }}=\sum_{p=1}^{o} \sum_{k=1}^{n} C W T_{\text {samp }, \mathrm{p}, k} \text { (out-of-basin) } / \sum_{p=1}^{q} \sum_{k=1}^{n} C W T_{\text {samp }, \mathrm{p}, \mathrm{k}} \text { (all CV locations). }
$$

## RESULTS

## General overview of 2019 CV inland recoveries and California ocean harvest

All of the 34,900 valid CWTs recovered in the CV during 2019 were from CV Chinook salmon releases. Most CWTs were brood year 2015 through 2017 releases (Table 6). About $89 \%$ of all $C W T_{\text {total }}$ were fall-run, followed by spring-run (7\%) and late-fall-run (3\%) salmon releases. Only $2 \%$ of $C W T_{\text {total }}$ were winter-run, some of which were collected from the first cohort of spawners to return to CFH as part of the FWS Battle Creek winter-run Jumpstart program (age-2). The remaining winter-run CWTs were all collected in the upper Sacramento River, which includes the Keswick Dam Fish Trap (KES) where winter-run are collected for broodstock purposes at Livingston Stone National Fish Hatchery (LSH). The majority of fall-run CWT total recovered in the CV were age-3 (76\%) and age-2 (21\%) fish.

Most of the 20,000 valid CWT recoveries from the 2019 California ocean harvest were CV salmon releases belonging to brood year 2016 (Table 7; one age-7 and five experimental San Joaquin fall-run removed). Approximately $96 \%$ of all $C W T_{\text {total }}$ in the ocean harvest were CV fall-run, followed by CV spring-run (1\%), CV late-fall-run (1\%), and CV winter-run ( $0.2 \%$ ) salmon. The remaining $2 \%$ of California ocean harvest CWT total originated primarily from the Klamath-Trinity Basin and Smith River in northern

California, the Rogue and Elk rivers in Oregon, and the Columbia River Basin. Most of the hatchery-origin fish in the California ocean harvest were age-3 fish (91\%), distantly followed by age-2 (5\%) and age-4 (3\%) fish.

Over two-thirds of the 1,700 valid CWT recoveries from the 2019 Oregon ocean harvest (south of Cape Falcon) were CV fall-run salmon releases (Table 8; one age-6 removed), which composed $71 \%$ of all $C W T_{\text {total. }}$. Recoveries of other CV run types were scarce off Oregon. Non-CV stocks made up $29 \%$ of the Oregon ocean harvest $C W T_{\text {total }}$, with most originating from the Columbia River Basin, coastal streams in Oregon, and the KlamathTrinity Basin. Most of the hatchery-origin fish in the Oregon ocean harvest were age-3 (79\%) and age-4 (18\%) fish.

## 1. Proportion of Hatchery- and Natural-origin Salmon in CV Escapement

During 2019, approximately 146,400 fall-run Chinook salmon returned to spawn in the CV natural areas included in these analyses (Table 9, Fig. 2). There were an additional 4,300 fall-run salmon that spawned in natural areas of tributaries that are excluded here because sample rates and resultant CWT recoveries were too low to produce reliable results. The proportion of hatchery-origin salmon in those areas sampled varied throughout the CV. The lowest fall-run hatchery proportion occurred in Butte Creek (0\%), followed by the upper Sacramento River mainstem (5\%), Tuolumne River (17\%), and Clear Creek (18\%). The highest fall-run hatchery proportion occurred in the American River (94\%), followed by Battle Creek (90\%) and the Mokelumne River (73\%). The total CV fall-run hatchery proportion for all natural areas that were adequately sampled during 2019 was $53 \%$.

One of the upper Sacramento Basin tributaries included in these analyses is Battle Creek, however the hatchery proportion was estimated using a surrogate since a carcass survey or CWT recovery program has not occurred in this waterway since 2005. The hatchery contribution and CWT release type composition in the Battle Creek fall-run escapement is assumed equivalent to the hatchery fall-run return sampled at CFH (K. Niemela, FWS, pers. comm.).

The hatchery proportion of the 62,100 fall-run salmon returning to the five CV hatcheries ranged from $53 \%$ to $90 \%$ (Table 9, Fig. 3). The fall-run hatchery proportion for all CV hatcheries combined was $79 \%$. The spring-run return to FRH and the late-fall-run return to CFH were almost entirely hatchery-origin salmon ( $95 \%$ and $98 \%$, respectively).

To help differentiate the hatchery composition, all CV release types from the same stock, run, and hatchery use the same shade of color in the pie chart figures: Blue = Sacramento River Basin fall-run releases, Green = San Joaquin Basin fall-run releases, Purple = Central Valley spring-run releases, Yellow = Sacramento River winter-run releases, and Orange = Central Valley late-fall-run releases (Fig. 4). Additionally, select patterns are used to designate different release types. All bay/delta net pen releases contain black dots, while coastal net pen releases are designated with a crisscross pattern. Golden Gate releases are shown with horizontal stripes. In-basin releases do
not have any pattern. To present the data in a less complicated manner, several release types have been merged in the pie chart figures and many of the tables. Please refer to footnote b / in Table 9 for a description of which release types were merged.

## Upper Sacramento River Basin

At CFH in 2019, the fall-run spawning period was considered early October through late November, and the late-fall-run spawning period was considered early December through late February 2020. However, FWS staff ultimately parsed the final escapement into run types based on CWT recoveries and the dominant run type by date. All adclipped salmon were sampled during the entire run, and additionally during the late-fallrun period all unmarked salmon were electronically checked for CWTs. An additional 365 late-fall-run salmon were trapped at CFH after spawning operations ended. Also, 2019 was the first year of spawner returns to CFH for winter-run salmon that were spawned at LSH, raised at CFH, and released into North Fork Battle Creek as part of the FWS Jumpstart program.

Winter-, fall-, and late-fall-run returns to CFH were predominantly hatchery-origin salmon, as were fall-run spawners in Battle Creek where CFH is located. Natural-origin spawners composed most of the winter-, fall-, and late-fall-run returns to the upper Sacramento River mainstem, Clear Creek, and Mill Creek (Figs. 5, 6). Winter- and late-fall-run spawners collected at KES were primarily hatchery-origin fish. The proportion of hatchery-origin fish (prevalent release type shown in parentheses) at each of the following locations was:

- Winter-run returns CFH: $100 \%$ (SacW)
- Fall-run returns CFH: 90\% (CFHF)
- Late-fall-run returns CFH: 98\% (CFHL)
- Late-fall-run returns CFH (post-spawning): 99\% (CFHL)
- Winter-run spawners for broodstock KES: 62\% (SacW)
- Late-fall-run supplemental spawners KES: 74\% (CFHL)
- Winter-run spawners upper Sacramento River: $35 \%$ (SacW)
- Fall-run spawners upper Sacramento River: 5\% (CFHF)
- Late-fall-run spawners upper Sacramento River: 14\% (CFHL)
- Fall-run spawners Clear Creek: $18 \%$ (CFHF)
- Fall-run spawners Battle Creek: 90\% (CFHF)
- Fall-run spawners Mill Creek: $40 \%$ (CFHF)

## Butte Creek and Feather River Basin

In Butte Creek, both spring- and fall-run spawners were entirely of natural-origin. In the Feather Basin, spring- and fall-run returns to FRH and spawners in the Yuba River below Daguerre Point Dam (DPD) were predominantly of hatchery-origin, while spawners in the Feather River and Yuba River above DPD were relatively evenly distributed between hatchery- and natural-origin (Figs. 7, 8). The proportion of hatcheryorigin fish (prevalent release type shown in parentheses) at each of the following locations was:

- Spring-run spawners Butte Creek: 0\%
- Fall-run spawners Butte Creek: 0\%
- Spring-run returns FRH: 95\% (FRHS)
- Fall-run returns FRH: 68\% (FRHFn)
- Fall/spring-run spawners Feather River: $45 \%$ (FRHFn)
- Fall/spring-run spawners Yuba River above DPD: 50\% (FRHFn)
- Fall/spring-run spawners Yuba River below DPD: 76\% (FRHFn)

Appendix 5 provides the $F_{\text {samp }}$ calculation for natural area spawners in the Yuba River above DPD, which was based on a combination of ad-clips observed via video weir and CWTs recovered during carcass surveys.

## American River Basin

Fall-run returns to NIM and spawners in the American River were predominantly of hatchery-origin (Fig. 9). The proportion of hatchery-origin fish (prevalent release type shown in parentheses) at each of the following locations was:

- Fall-run returns NIM: 87\% (NIMFn)
- Fall-run spawners American River: $94 \%$ (NIMFn)

In prior versions of this report, CWTs that were collected from fish sampled on the NIM weir (i.e., "washbacks") were analyzed separately from those that were collected during carcass surveys downstream of the weir. This was done because salmon that were encountered upstream of the weir tended to exhibit an earlier run timing (e.g., strays from other hatcheries) since many of them would have migrated above the weir before it was put in place each year. Additionally, separate escapement estimates have been produced for NIM weir "washbacks" and the carcass survey downstream for almost 40 years. However, beginning in 2018, a single natural area escapement estimate has been reported annually utilizing mark-recapture methods and treating the entire American Basin (i.e., both upstream and downstream of the weir) as one system. So, these two escapement sectors are now merged and the same $F_{\text {samp }}$ is applied to CWTS recovered at both the weir and in the downstream carcass survey. This was the second year that fishing was permanently closed upstream of the NIM weir, so there were many carcasses encountered above the weir that would have likely been harvested under prior fishing regulations. Appendix 4 provides a comparison of raw CWT recoveries by release type between fish sampled upstream and downstream of the NIM weir in 2019.

## Mokelumne, Stanislaus, and Tuolumne rivers

Fall-run returns to MOK and Mokelumne River natural areas were predominantly hatchery-origin salmon. Spawners in the Stanislaus River were mostly of hatchery-origin by a small margin, while spawners in the Tuolumne River were predominantly of natural-origin (Fig. 10). The proportion of hatchery-origin fish (prevalent release type shown in parentheses) at each of the following locations was:

- Fall-run returns MOK: 89\% (MOKFn)
- Fall-run spawners Mokelumne River: 73\% (MOKFn)
- Fall-run spawners Stanislaus River: 54\% (MOKFn)
- Fall-run spawners Tuolumne River: 17\% (MERFn)

Appendix 6 provides the $F_{\text {samp }}$ calculation for Mokelumne River natural area spawners, which was based on a combination of ad-clips observed via video weir, ad-clips returning to MOK, and CWTs recovered during carcass surveys.

## Merced and upper San Joaquin rivers

Fall-run returns to MER were relatively evenly distributed between hatchery- and natural-origin salmon, and it was the lowest hatchery contribution observed since the CFM program was fully implemented. Natural area spawners in the Merced River were predominantly of natural-origin. Due to high flows in the San Joaquin River during spring 2019, spring-run spawners could volitionally return to the upper San Joaquin River via the Eastside Bypass. These spring-run spawners were predominantly hatchery-origin salmon (Fig. 11). The proportion of hatchery-origin fish (prevalent release type shown in parentheses) at each of the following locations was:

- Fall-run returns MER: 53\% (MERFn)
- Fall-run spawners Merced River: 24\% (MERFn)
- Spring-run spawners upper San Joaquin River: 94\% (SJOSx)

## 2. Contribution of CV Release Types to Total Salmon Escapement

In 2019, $57 \%$ of the 240,600 salmon that returned to the CV hatcheries and natural areas included in these analyses were hatchery-origin fish (Tables 9, 10). The hatchery release types that contributed the most to total CV escapement were CFH fall-run inbasin releases (14\%) followed by fall-run bay/delta net pen releases from FRH and MOK ( $9 \%$ and $7 \%$, respectively). MOK fall-run bay/delta net pen releases had the highest number of strays, while MOK fall-run coastal net pen and Golden Gate releases had the highest rates of straying (79\% and 76\%, respectively), closely followed by MER fall-run bay/delta net pen releases ( $75 \%$ ). About $14 \%$ of all recoveries occurred outside their basin-of-origin and ranged from $<1 \%$ to $79 \%$, depending on release type:

Hatchery-origin contribution by $R_{\text {type }}$ to total CV salmon escapement

| Rtype | Run | CWT total | \% total | \# Stray | $\%$ stray |

## 3. Hatchery Proportion and Contribution of CV Release Types to CV Sport Fishery

In 2019, 60\% of the 30,500 salmon harvested in the CV river sport fishery were hatchery-origin fish (Table 9; Figs. 12, 13). The Mokelumne River sport fishery was excluded from these analyses because few fish were sampled ( $n=11$; total harvest=118) and no CWTs were recovered. The proportion of hatchery-origin fish (prevalent release type[s] shown in parentheses) in each of the following fisheries was:

- Upper Sacramento River fall-run harvest: 55\% (CFHF)
- Lower Sacramento River fall-run harvest: $67 \%$ (FRHFgg, MOKFn)
- Feather River fall-run harvest: $62 \%$ (FRHFn)
- American River fall-run harvest: 64\% (MOKFn)
- Upper Sacramento River late-fall-run harvest: 55\% (CFHL)

Of all hatchery release types, CFH fall-run in-basin releases contributed the most (21\%) to the total CV sport harvest, followed by FRH fall-run Golden Gate and bay/delta net pen releases ( $12 \%$ and $11 \%$, respectively). In-basin releases were primarily harvested in their basin-of-origin or the lower Sacramento River (which all CV stocks must traverse before reaching their basin-of-origin). Conversely, net pen and Golden Gate releases were harvested out-of-basin at much higher rates (Tables 9, 10).

| Hatchery-origin contribution by $\mathrm{Rtype}^{\text {to total }} \mathrm{CV}$ river harvest |  |  |  |

|  | Total | 18,436 | 60\% |

## 4a. Relative Recovery and Stray Rates of CV Release Types in Total Escapement

Release strategies vary among hatcheries from year to year. This variability has often been in response to annual fluctuations in the abundance of certain stocks or differing policies among agencies with respect to best release practices. The 2015 through 2017 brood year releases were more consistent than release types analyzed in earlier CFM reports (Kormos et. al. 2012, Palmer-Zwahlen and Kormos 2013, 2015) and very few "mixed strategy" releases were identified (Table 3).

Table 11 summarizes total CWT samp recoveries and the escapement recovery rate, $R_{\text {type }}$, (in-basin and stray) for all release types collected in the CV escapement and ocean fisheries during 2019. The CWTs collected in the CV river sport fishery are not included since it is not possible to ascertain the location where these fish would have eventually spawned. Recovery rates are standardized utilizing total CWT samp recoveries per 100,000 tagged salmon released. Release types with less than 15,000 total fish released with CWTs are not reported below since just a few recoveries could result in relatively large recovery and stray rate estimates.

Figures 14 and 15 provide a graphical representation of $R_{\text {type }}$ for Sacramento River fallrun Chinook salmon and other CV stocks, respectively, and include the total number of salmon released with CWTs for each release type. Fall-run salmon that were released offsite, both those acclimated in net pens and those released directly into the water, had higher CV recovery rates than their respective in-basin releases, but offsite releases also had higher stray rates than their in-basin counterparts.

## Age-2 CV Escapement Recovery and Stray Rates

| $R_{\text {type }}$ | Brood year | Run | \# Recoveries per <br> 100K Released | \# Strays per <br> 100K Released | \% stray |

## 4b. Relative Recovery Rate of CV Release Types in the Ocean Harvest

The total recovery rate of CV hatchery releases in California and Oregon (south of Cape Falcon) sport and commercial ocean salmon fisheries varied by age and release type (Table 11). A higher percentage of age-2 CV hatchery salmon were recovered in the ocean sport fishery (Fig. 16) due to the smaller size limits in effect during 2019 compared to those for the commercial fishery (Table 2).

Age-2 Ocean Harvest Recovery Rate; Percent taken in Sport Harvest

## 5. Hatchery Proportion and Contribution of CV Release Types to Ocean Salmon Fisheries

Over half of the 393,600 Chinook salmon harvested in California and Oregon (south of Cape Falcon) ocean salmon fisheries were hatchery-origin fish (Fig. 17). The most prevalent CV release types recovered off both states were CFH fall-run in-basin releases followed by fall-run bay/delta net pen releases from FRH, NIM, and MOK.

Hatchery-origin contribution by $\mathrm{R}_{\text {type }}$ to CA and OR ocean harvest

| R $_{\text {type }}$ | Run | CWT $_{\text {total }}$ | \% harvest |
| :--- | :--- | ---: | :---: |
| CFHF | Fall | 61,303 | $16 \%$ |
| CFHFn | Fall | 24 | $<1 \%$ |
| FRHF | Fall | 5,589 | $1 \%$ |

| Other CV | Non-fall |  | 4,942 |
| Non-CV |  | 7,293 | $1 \%$ |
|  |  | Total | 208,588 |

## California ocean sport fishery

California anglers harvested approximately 88,500 Chinook salmon in the ocean sport fishery during 2019. The total contribution of hatchery-origin salmon to the California ocean sport fishery was $58 \%$, ranging from $56 \%$ to $58 \%$ of the total harvest depending on major port area (Fig. 18). Most of the harvest occurred in the San Francisco port area (64\%), followed by the Monterey (26\%), Eureka/Crescent City (6\%), and Fort Bragg (4\%) port areas (Table 12).

Of all hatchery release types, CFH fall-run in-basin releases contributed the most (15\%) to the total California ocean sport harvest, followed by FRH fall-run bay/delta net pen and Golden Gate releases (10\% and 7\%, respectively). Non-CV releases composed 1\% of the total sport harvest (Table 13).

Hatchery-origin contribution by $\mathrm{R}_{\text {type }}$ to CA ocean sport harvest

| Rtype | Run | CWT $_{\text {total }}$ | \% harvest |
| :--- | :--- | ---: | :---: |
| CFHF | Fall | 13,472 | $15 \%$ |
| CFHFn | Fall | 0 | $0 \%$ |

| MERF | Fall | 89 | $<1 \%$ |
| MERFn | Fall | 541 | $1 \%$ |
| SacW | Winter |  | 247 |
| FRHS | Spring | 883 | $<1 \%$ |
| SJOSx | Spring |  | 26 |
| CFHL | Late-fall |  | 478 |
| Non-CV |  | 606 | $<1 \%$ |
|  |  | Total | 50,895 |

## California ocean commercial fishery

California trollers harvested almost 271,500 Chinook salmon in the commercial ocean fishery during 2019. The total contribution of hatchery-origin salmon to the California commercial ocean fishery was 53\%, ranging from 45\% to 55\% of the total harvest depending on major port area (Fig. 19). Most of the harvest occurred in the San Francisco port area (58\%), followed by the Monterey (36\%), Fort Bragg (3\%), and Eureka/Crescent City (2\%) port areas (Table 14).

Of all hatchery release types, CFH fall-run in-basin releases contributed the most (16\%) to the total California commercial harvest, followed by fall-run bay/delta net pen releases from NIM, MOK, and FRH ( $7 \%, 6 \%$, and $6 \%$, respectively) and NIM fall-run inbasin releases (6\%). Non-CV releases contributed $1 \%$ to the total commercial harvest (Table 15).

## 6. Relative Recovery and Stray Rates of Fall-run Experimental and Net Pen Release Types

In 2019, CWTs from many fall-run experimental and net pen release types were recovered in the CV escapement and ocean harvest, and this section will focus on those from brood years 2015 through 2017 (ages 2-4). Experimental releases include barge studies that utilized approximately 600,000 fall-run salmon from MOK, and nonacclimated Golden Gate releases at Fort Baker which utilized approximately 3.5 million and 200,000 fall-run salmon from FRH and MOK, respectively.

Net pen releases can be categorized into either bay/delta or coastal releases. Bay/delta net pen releases include those that are released in the western Delta (CFH, MOK, and MER), and those that are released where the Carquinez Strait meets San Pablo Bay (FRH and NIM). Coastal net pen releases include those coordinated by the Coastside Fishing Club in Pillar Point and those coordinated by the Monterey Bay Trout and Salmon Project in Santa Cruz.

The experimental and net pen releases recovered in 2019 are differentiated into the following release types:

- FRHFn Feather River Hatchery Fall-run bay/delta net pens
- FRHFgg Feather River Hatchery Fall-run Golden Gate releases (no net pen acclimation)
- NIMFn Nimbus Fish Hatchery Fall-run bay/delta net pens
- MOKFn Mokelumne River Hatchery Fall-run bay/delta net pens
- MOKFnp Mokelumne River Hatchery Fall-run coastal net pens - Pillar Point
- MOKFns Mokelumne River Hatchery Fall-run coastal net pens - Santa Cruz
- MOKFgg Mokelumne River Hatchery Fall-run Golden Gate releases (no net pen acclimation)
- MOKFbb Mokelumne River Hatchery Fall-run barge study: trucked and released in SF Bay
- MOKFbg Mokelumne River Hatchery Fall-run barge study: barged to SF Bay and released
- MOKFbr Mokelumne River Hatchery Fall-run barge study: released in-river (Mok R)
- MERFn Merced River Hatchery Fall-run bay/delta net pens

## Central Valley Escapement

The CV escapement recovery rate and percent stray for all fall-run experimental and net pen releases are included below to allow direct comparison among these release types (Table 16, Fig. 20).

Age-2 CV Escapement Recovery and Stray Rates

## 2019 CFM ANALYSES KEY POINTS

- A majority (57\%) of the total 2019 CV salmon escapement (all run-types) was hatchery-origin fish. This was a decrease of $19 \%$ in hatchery contribution from the 2018 escapement and was the lowest estimate since the CFM program was fully implemented. Between 2010 and 2018, the hatchery contribution to the total CV escapement averaged $76 \%$ and ranged between $65 \%$ and $88 \%$. The decrease observed in 2019 suggests continued improvement in natural-origin production following the drought that occurred during 2012-2016. Also, the 2016 fall-run brood, which were age-3 in 2019, hatched during a very wet winter which may have boosted natural-origin juvenile production and survival. CFH fall-run in-basin releases had the highest contribution (14\%) to the total 2019 CV escapement, with FRH and MOK fallrun bay/delta releases being the next highest contributors ( $9 \%$ and $7 \%$, respectively).
- The highest stray rates all occurred with offsite MOK and MER releases. MOK fall-run coastal releases strayed the most (79\%), followed by MOK fall-run Golden Gate (76\%; includes those that were barged to the Golden Gate), MER fall-run offsite (75\%; includes bay/delta net pen and non-acclimated), and MOK fall-run bay/delta (47\%) releases. Offsite releases from other hatcheries strayed at much lower rates, with the lowest being NIM fall-run bay/delta releases (5\%), followed by FRH fall-run bay/delta and Golden Gate releases ( $11 \%$ and $13 \%$, respectively). There were no inland recoveries of offsite CFH releases, although any such recoveries would have been age-5 only.
- Salmon escapement into CV hatcheries was predominately hatchery-origin fish. At all CV hatcheries except MER, the majority of their return was composed of their respective releases. But only $38 \%$ of the return to MER consisted of fish that were produced there, with the remainder consisting of natural-origin salmon (47\%) and stray hatchery-origin salmon (16\%). This was the lowest hatchery contribution (53\%) observed at MER since the CFM program was fully implemented, as was the hatchery contribution in Merced River natural areas (24\%). The out-of-basin hatchery return at NIM was also quite high (28\%), with most of those strays originating from MOK.
- Hatchery contributions to natural area escapements were generally much lower than has been observed since the CFM program was fully implemented. For fall-run specifically, the hatchery contribution across all CV natural areas was $53 \%$ compared to the $2010-2018$ average of $71 \%$ (range: $55 \%-81 \%$ ). As mentioned above, this is likely reflective of improved natural-origin production and survival during the wet winter of 2016/17. Most natural area spawning escapements were primarily natural-origin fish. The exceptions were the spring-run escapement to the upper San Joaquin River and the fall-run escapements to Battle Creek and the Yuba, American, Mokelumne, and Stanislaus rivers. In all rivers that contain hatcheries, most of the hatchery-origin components consisted of release types from their respective hatcheries. However, strays from out-of-basin hatcheries made noticeable contributions to the natural area escapements in the American and Merced rivers (37\% and 45\% of the hatchery-origin
components, respectively), with MOK fall-run bay/delta releases making the most notable contributions ( $18 \%$ and $30 \%$ of the hatchery-origin components, respectively).
- Fall-run escapement in the upper Sacramento River mainstem was dominated by natural-origin salmon. The hatchery contribution in 2019 (5\%) was the lowest by a wide margin since the CFM program was fully implemented. Between 2010 and 2018, the hatchery contribution in the upper Sacramento River mainstem averaged 39\% and ranged between $20 \%$ and $68 \%$. CFH in-basin releases composed the bulk of the hatchery-origin portion of the Sacramento River mainstem fall-run escapement.
- Fall/spring-run escapement to the natural spawning areas of the Feather River was mostly natural-origin salmon by a small margin. FRH fall-run bay/delta and Golden Gate releases had the highest contributions of any release type. Spring-run releases from FRH only formed 6\% of the escapement but were the next highest contributor. Inbasin fall-run releases from FRH composed $4 \%$ of the escapement.
- Of the total fall/spring-run escapement in the Yuba River, $80 \%$ occurred above DPD and $20 \%$ occurred below. The escapement above DPD was evenly distributed between hatchery- and natural-origin salmon, while the escapement below DPD was predominantly hatchery-origin salmon. FRH fall-run bay/delta releases composed the bulk of the hatchery-origin components in both sectors.
- Fall-run escapement to the natural spawning areas of the American River was dominated by hatchery-origin salmon. NIM bay/delta and in-basin releases were the highest-contributing release types, followed by stray MOK bay/delta releases.
- Fall-run escapement to the natural spawning areas of the Mokelumne River was primarily hatchery-origin salmon, with MOK bay/delta releases composing over half of the total escapement.
- Fall-run escapement to the Stanislaus River was mostly hatchery-origin salmon by a small margin, with stray MOK bay/delta releases composing the bulk of the hatcheryorigin component. Conversely, the fall-run escapement to the Tuolumne River was predominantly natural-origin salmon, with stray MER and MOK bay/delta releases being the highest contributors.
- Fall-run escapement to the natural spawning areas of the Merced River was primarily natural-origin salmon. Similar to the return at MER, this was the lowest hatchery contribution observed since the CFM program was fully implemented. MER bay/delta releases composed half of the hatchery-origin component.
- For age-2 fall-run salmon, FRH Golden Gate releases had the highest CV escapement recovery rate for their cohort, followed by MER bay/delta, MOK coastal, FRH bay/delta, and NIM bay/delta releases. Offsite releases from MOK and MER had the highest stray rates among this cohort, with MOK coastal and MER bay/delta releases straying at particularly high rates. Releases from other hatcheries and MOK in-basin releases all had substantially lower stray rates.
- For age-3 fall-run salmon, NIM bay/delta and FRH Golden Gate releases had the highest CV escapement recovery rates for their cohort, followed by MOK Golden Gate, FRH bay/delta, NIM in-basin, and FRH in-basin releases. Offsite releases from MOK had the highest stray rates among this cohort, with MOK coastal, Golden Gate, and barge study (excluding the in-river control group) releases straying at particularly high rates. Releases from other hatcheries and MOK in-basin releases all had substantially lower stray rates.
- For age-4 fall-run salmon, FRH bay/delta releases had the highest CV escapement recovery rate for their cohort, followed by MOK barge study releases (excluding the inriver control group). Offsite releases from MOK and MER had the highest stray rates among this cohort, and MER non-acclimated trucked releases returned entirely to nonnatal basins (i.e., stray rate of 100\%). MER bay/delta, MOK coastal, and MOK bay/delta releases also strayed at very high rates. Releases from other hatcheries and MOK in-basin releases all had substantially lower stray rates.
- While most (60\%) of the total CV river sport harvest was comprised of hatchery-origin salmon, it was the lowest hatchery contribution since the CFM program was fully implemented. Between 2010 and 2018, the hatchery contribution to the CV river sport harvest averaged $76 \%$ and ranged between $66 \%$ and $84 \%$. Similar to the CV escapement, the low hatchery contribution in the inland harvest may be due to improved natural-origin production and survival for the 2016 fall-run brood. The highest-contributing hatchery release types were CFH fall-run in-basin, FRH fall-run Golden Gate, and FRH fall-run bay/delta releases. The American River was the only fishery sector where in-basin hatchery fish did not compose a majority of the harvest, as NIM releases only accounted for $27 \%$ of the catch. Strays from MOK and FRH represented $22 \%$ and $15 \%$ of the American River sport harvest, respectively.
- Over half of the California ocean sport and commercial harvest was composed of hatchery-origin fish. CFH fall-run in-basin releases had the highest contribution to the total harvest in both fisheries. There were also moderate contributions from FRH, NIM, and MOK fall-run bay/delta releases, as well as FRH Golden Gate and NIM in-basin releases. Non-CV hatchery production contributed moderately to the ocean harvest in the Eureka/Crescent City port area but contributed very little in port areas to the south which combined accounted for $94 \%$ and $98 \%$ of the total California sport and commercial ocean harvest, respectively.
- Ocean recovery rates for age-3 NIM fall-run releases were much higher than has previously been observed, and the bay/delta releases from that brood had the highest ocean recovery rate of any release type analyzed in this report. The ocean recovery rates for both age-3 NIM bay/delta and in-basin releases were much higher than has been observed in any bay/delta or in-basin release group, respectively, from any CV hatchery since the CFM program was fully implemented.
- Golden Gate fall-run releases from FRH (ages 2 and 3) and MOK (age-3 only) also had very high ocean recovery rates, in addition to the high CV escapement recovery
rates previously mentioned. For the ages at which they were present, both their CV and ocean recovery rates exceeded those of the bay/delta and coastal net pen releases from the same hatchery and brood. The sole Golden Gate release from MOK strayed at a substantially higher rate than those produced at FRH.
- Coastal fall-run releases, all of which were from MOK, also had very high ocean recovery rates at all ages. The age-2 CV escapement recovery rate was also high for coastal fall-run releases, but the age-3 CV recovery rate was quite low. Among the coastal release locations, which in 2019 only co-occurred in age-3 fish, the Pillar Point release had much higher CV and ocean recovery rates than the Santa Cruz release. While the age-3 CV recovery rates were low for both release locations, the Santa Cruz CV recovery rate was noticeably lower. The Santa Cruz release had much lower CV and ocean recovery rates than any other offsite release from that brood.
- This is the third report in the series that has recovery data for non-experimental FRH fall-run in-basin releases, providing another year of recovery and stray rate comparisons between in-basin and out-of-basin FRH fall-run releases from the same brood. Results from 2019 suggest lower survival but less straying for in-basin releases. The differences in survival were stark for the 2017 and 2015 broods (i.e., ages 2 and 4), as there were only 3 CV and no ocean recoveries of age-2 FRH inbasin releases, and no recoveries whatsoever of age-4 FRH in-basin releases. That translates to age-2 CV and ocean recovery rates of 1 and 0 CWTs per 100,000 released, respectively, and age-4 recovery rates of 0 for both. Conversely, FRH bay/delta releases had age-2 CV and ocean recovery rates of 126 and 52 CWTs per 100,000 released, respectively, and age-4 recovery rates of 30 and 20, respectively. Age-2 CV and ocean recovery rates were even higher for FRH Golden Gate releases at 227 and 88 CWTs per 100,000 released, respectively. While offsite FRH releases from those two broods did have higher stray rates than in-basin releases, they were not particularly high ranging between $1 \%$ and $8 \%$. There were many more age-3 recoveries of all FRH release types which provides for a more robust comparison, and while the same general pattern was still observed, age-3 recovery rates were much closer between in-basin and bay/delta releases than they were for the other ages. Specifically, age-3 CV and ocean recovery rates for FRH in-basin releases were 334 and 541 CWTs per 100,000 released, respectively, compared to 429 and 737, respectively, for bay/delta releases. This similarity in recovery rates was also observed for this brood in the 2018 report (i.e., as age-2 fish), suggesting adequate in-river conditions during the winter of 2016/17, which as previously stated was a very wet winter. Despite this similarity between age-3 in-basin and bay/delta releases, age-3 Golden Gate releases had much higher CV and ocean recovery rates than either, at 836 and 1,644 CWTs per 100,000 released, respectively. Stray rates for this brood of FRH fall-run were higher than they were for the other broods, at $0.2 \%$ for in-basin releases, $17 \%$ for bay/delta releases, and $16 \%$ for Golden Gate releases.
- The age-3 winter-run CV recovery rate of 1,896 CWTs per 100,000 released was more than four times higher than the next highest recovery rate that has been observed in these reports. Between 2012 and 2018, the age-3 winter-run CV recovery rate
averaged 254 CWTs per 100,000 released and ranged between 72 and 425. This winter-run brood likely benefitted from the wet winter of 2016/17. Additionally, the 2019 winter-run escapement to the upper Sacramento River was the highest escapement observed since 2006 (PFMC 2021).
- 2019 was the first year that winter-run salmon released into North Fork Battle Creek as part of the FWS Jumpstart program began to return as spawners and contribute to ocean harvest (age-2 only). The CV and ocean recovery rates for this release type were both lower than for winter-run released into the upper Sacramento River, although the CV recovery rates were not drastically different. Among the winter-run that returned to the CV in 2019, those that were released into Battle Creek returned entirely to Battle Creek, and those that were released into the upper Sacramento River returned entirely to the upper Sacramento River.
- This is the first report in the series that includes data for the upper San Joaquin River mainstem spring-run escapement. Due to high flows during spring 2019, spring-run spawners could volitionally return to the upper San Joaquin River via the Eastside Bypass. In most years such passage does not exist, and spawners must be trapped further downstream and translocated to the upper San Joaquin River. The spring-run escapement to this sector was overwhelmingly hatchery-origin salmon, although that is expected this early in the reintroduction effort.
- CV and ocean recoveries of winter- and spring-run releases were predominantly age-3 salmon, while recoveries of late-fall-run releases were more evenly distributed between ages 3 and 4. In the CV, approximately two-thirds and one-third of the late-fall-run recoveries were ages 3 and 4, respectively, whereas it was vice versa in the ocean harvest.
- Among the age-3 recoveries of barge study releases, salmon that were barged from the Mokelumne River to the Golden Gate had the highest CV and ocean recovery rates but also the highest stray rate. Salmon that were trucked to Sausalito and then barged to the Golden Gate had similar but slightly lower stray and ocean recovery rates, and a much lower CV recovery rate, than those that were barged the entire route. Salmon that were released directly into the Mokelumne River as part of the control group had a substantially lower stray rate but also a much lower ocean recovery rate than either of the other treatments, and also a much lower CV recovery rate than those that were barged the entire route.
- Among the age-4 recoveries of barge study releases, salmon that were barged from the Mokelumne River to the Golden Gate had the highest CV recovery rate but also the highest stray rate. Salmon that were trucked to Tiburon and then barged to the Golden Gate had the highest ocean recovery rate, although it was similar to those that were barged the entire route. Both of these treatments exhibited much lower stray rates than the same treatments in the age-3 cohort. There were no recoveries whatsoever of salmon that were released directly into the Mokelumne River as part of the control group for this brood.

## CONCLUSION

A primary goal of this report is to provide information that will be useful in California salmon management, including CV hatchery assessment. As with each of the previous nine CFM reports, the estimates of hatchery contribution and recovery rate by release type presented in this report should be viewed as a "single year snapshot" of salmon escapement and harvest in the CV and California ocean fisheries during 2019. Although no discussion section is included, as in earlier CFM reports covering the 2010, 2011, and 2012 escapement and harvest years, the authors plan to further analyze these data as these and additional tagged broods become complete. This report contains the data and analyses needed to determine the contribution of hatchery- and natural-origin salmon to hatchery and natural areas throughout the CV, evaluate hatchery release strategies and programs, improve California ocean and river salmon fisheries management, evaluate the effectiveness of habitat restoration, and determine if other goals of the CFM program are being met on an annual basis. This information, combined with other tools such as cohort reconstruction and harvest models, will allow resource managers to determine the total contribution of various release strategies to CV escapement and to ocean and inland fisheries by time and area.

The CFM program should be continued with the current design to provide comparable, consistent data needed for hatchery and harvest management. Securing permanent and comprehensive inland and ocean funding for this marking, tagging, monitoring, and evaluation program is critical. Such funding is essential to providing complete analyses of recovery and stray rates across release strategies, and will allow critical data to be available by February of each year to manage CV salmon stocks, hatchery production, and California ocean and river fisheries using the most recent information, similar to the Klamath Basin fall-run Chinook salmon management process.

## ACKNOWLEDGEMENTS

We express sincere appreciation to the myriad of staff among many agencies that work tirelessly in the field to gather the necessary data and CWT recoveries that provide the basis for this report. They are too numerous to name individually, but without each of them, this valuable analysis would not be possible. We again thank the following agencies for providing 2019 CV escapement estimates and their respective salmon heads or CWT recoveries: CDFW, DWR, FWS, PSMFC, EBMUD, and YARMT. Special thanks are extended to staff at the following hatcheries for their cooperation in this monitoring effort: Coleman National Fish Hatchery, Feather River Hatchery, Nimbus Fish Hatchery, Mokelumne River Hatchery, Merced River Hatchery, and Livingston Stone National Fish Hatchery.

Special kudos are extended to both CDFW Santa Rosa and Sacramento CWT labs for processing over 43,000 salmon heads and recovering, reading, and validating most of the CWTs used in these analyses. Personal thanks are extended to FWS staff Kevin Offill, Kevin Niemela, Austin Demarest, and Heather Swinney for providing their agency's CWT data and for answering numerous questions for this report, and to PSMFC staff Duane Massa and CDFW staff Audrey Dean, Doug Killam, Tracy Grimes, Pat Ferguson, Matt Bigelow, Brian Erlandsen, Anna Kastner, Michael Paccassi, and Steve Tsao for answering questions and providing additional information pertaining to their CV sectors.

Thanks to the following individuals for providing internal review and text edits for this report: CDFW staff Grace Ghrist and Audrey Dean.

We, as always, want to acknowledge Stan Allen (PSMFC) and Alice Low (CDFW retired) for their efforts in developing the CFM program and facilitating its funding, staffing, tagging, and coordination needs. Funding for most of the sampling and CWT processing provided by BOR, CDFW, DWR, EBMUD, SFRA, and YARMT.

## LIST OF APPENDICES

Appendix 1. Sample expansion factors for Central Valley salmon carcass surveys collecting fish condition in 2019.

Appendix 2. Alternative 2019 CWT recovery and stray rates (recoveries per 100,000 CWTs released) of CFH and FRH releases.

Appendix 3. Alternative CWT recovery rates for CFH and FRH releases by age in 2019.
Appendix 4. Comparison of raw CWT recoveries by release type between fish sampled in natural areas above and below the NIM weir in 2019.

Appendix 5. Sample expansion for CWTs recovered in the Yuba River above Daguerre Point Dam in 2019.

Appendix 6. Sample expansion for CWTs recovered in the Mokelumne River above Woodbridge Dam in 2019.

Table 1a. Estimation and sampling methods used for the 2019 CV Chinook hatchery escapement.

| Sampling Location | Estimation and Sampling Methods | Agency |
| :---: | :---: | :---: |
| Hatchery Spawners |  |  |
| Coleman National Fish Hatchery (CFH) Fall and Late-Fall (2020) | Direct count. All fish examined and bio-sampled ${ }^{\text {a/ }}$ for fin-clips, tags, marks. All adclipped fish sampled and heads collected for CWT recovery. Access upstream of the hatchery closed beginning Aug 1. The fall-run period is considered early Oct through late Nov and the late-fall-run period is considered early Dec through late Feb. However, the final escapement is ultimately parsed into run types based on CWT code recoveries and dominant run type by date. During the late-fall-run period, all unmarked fish are electronically checked for CWTs. Some untagged phenotypic late-fall-run fish are released into Battle Creek above CFH. Grilse cutoff: 650 mm females, 680 mm males fall; 510 mm females, 540 mm males late-fall. | FWS |
| CFH Winter and Late-Fall (2020) Fish Trap | Direct count of winter-run which are identified by left pelvic fin-clips and CWTs, or late-fall-run that are trapped after CFH spawning operations cease. All fish examined and bio-sampled for fin-clips, tags, marks. All ad-clipped fish sampled and heads collected for CWT recovery, and all unmarked fish are electronically checked for CWTs. Any untagged phenotypic late-fall-run fish are released into Battle Creek above CFH. Any additional fish observed on video after trap removal are examined for fin-clips and added to escapement estimates. Grilse cutoff: 510 mm females, 540 mm males late-fall; all winter-run were grilse in 2019. | FWS |
| Keswick Fish Trap Winter and Late-Fall (2020) | Direct count. All fish examined and bio-sampled for fin-clips, tags, marks. During Feb-Jul, all unmarked fish electronically sampled for presence of CWT and genetically tested to ensure winter-run broodstock. To promote genetic integrity of CFH broodstock, Keswick fish trap was also utilized to collect late-fall-run during Dec-Feb. Grilse cutoff: 610 mm females, 670 mm males winter; 510 mm females, 540 mm males late-fall. | FWS |
| Feather River Hatchery (FRH) Spring and Fall | Direct count. All fish examined for fin-clips, tags, marks. Fish arriving at the hatchery May 6 - Jun 28 ( $n \sim 5,945$ ) were considered "spring-run" and marked with uniquely-numbered dart tags prior to release back into the Feather River. Only fish marked with dart tags returning to FRH in fall were spawned as spring-run. All remaining fish were considered fall-run. FRH fish ladder opened Sep 13 and spring spawning began Sep 17. All spring-run fish bio-sampled. Fall spawning occured on Oct 1 for the cold water program and began normally on Oct 9 . Fall spawning ceased on Nov 8 . Systematic random bio-sample $\sim 20 \%$ of all fish for fall-run. All adclipped fish were sampled and heads collected for CWT recovery. Grilse cutoff: 650 mm spring and fall. | CDFW |
| Nimbus Fish Hatchery (NIM) Fall | Direct count. NIM ladder open Nov 4 - Jan 7. All fish examined for fin-clips, tags, marks. Systematic random bio-sample of $20 \%$ of total fish. All ad-clipped fish sampled and heads collected for CWT recovery. Grilse cutoff: 685 mm . | CDFW |
| Mokelumne River Hatchery (MOK) Fall | Direct count. MOK open Oct 15 - Jan 16. All fish examined for fin-clips, tags, marks. Systematic random bio-sample $20 \%$ of total fish\%. All ad-clipped fish sampled and heads collected for CWT recovery. Grilse cutoff: 640 mm females, 680 mm males. | CDFW |
| Merced River Hatchery (MER) Fall | Direct count. MER open Oct 17 - Dec 5. All fish examined for fin-clips, tags, marks. All ad-clipped fish were sampled and heads processed for CWT recovery. Grilse cutoff: 610 mm females, 670 mm males. | CDFW |

[^0]Table 1b. Estimation and sampling methods used for the 2019 CV Chinook natural escapement. (Page 1 of 2)

| Sampling Location | Estimation and Sampling Methods | Agency |
| :---: | :---: | :---: |
| Natural Spawners |  |  |
| Upper Sacramento River Mainstem Winter, Fall, and Late-Fall (2020) | Population estimate for each run produced utilizing five-step process: <br> 1) Superpopulation modification of the Cormack-Jolly-Seber mark-recapture estimate using all females within carcass survey area (Balls Ferry Bridge to Keswick Dam). 2) Total female escapement estimate in upper Sacramento River is derived using expansions for females spawning outside of the survey area (Princeton to Balls Ferry) through aerial redd surveys. 3) Adult male escapement estimated using adult sex ratio of live fish counts at CFH or Keswick Trap. 4) Grilse escapement estimated using survey ratio of fresh adult males to fresh grilse. 5) Addition of any fish removed for hatchery brood stock purposes. All fish in carcass survey examined for fin-clips, tags, marks, and condition (e.g., fresh, non-fresh, skeleton). Biodata ${ }^{\text {a/ }}$ collected from all fresh fish. Systematic random bio-sample may occur if carcass counts expected to be high. All ad-clipped fish (fresh and non-fresh), including "unknown" ad-clipped status, were sexed, measured and heads collected for CWT recovery. Grilse cutoff: 610 mm females, 680 mm males winter; 640 mm females, 720 mm males fall; 610 mm females, 620 mm males late-fall. | CDFW, FWS |
| Clear Creek Fall | Video Station count used to estimate population. Supplemental bio-sampling survey used to estimate biological characteristics of the population (age, sex, hatchery-origin, spawn sucess). All fish in carcass survey examined for fin-clips, tags, marks, and condition (e.g., fresh, non-fresh, skeleton). Bio-data collected from all fresh fish. All ad-clipped fish (fresh and non-fresh), including "unknown" ad-clipped status, were sampled and heads collected for CWT recovery. Bio-sampling data from CFH used as a surrogate. | CDFW, <br> FWS |
| Cow Creek Fall | Video weir count in lower creek used to determine total escapement. Kayak surveys conducted to collect bio-data from fresh fish. Opportunistic collection of CWTs, however only 20 carcasses observed. Bio-sampling data from CFH used as a surrogate. | CDFW |
| Battle Creek Fall | Video weir count (Aug 19-Dec 1) in lower creek used to determine total fall-run escapement. Natural fall-run escapement into Battle Creek calculated by substracting CFH fall-run return from total run. Surrogate CWTs based on hatchery proportion and CWT composition of CFH fall-run return. Bio-sampling data from CFH used as a surrogate. | CDFW |
| Cottonwood Creek Fall | Video weir count (Sep 24 - Dec 15) in lower creek used to determine total escapement. Kayak surveys conducted to collect bio-data from fresh fish, however only seven carcasses were observed. Bio-sampling data from CFH used as a surrogate. | CDFW |
| Mill Creek Fall | Video counts at Ward Dam in lower Mill Creek plus expanded redd count between Ward Dam and the Sacramento River confluence used to determine total escapement. Bio-sampling surveys conducted to collect bio-data from fresh fish. All ad-clipped fish (fresh and non-fresh), including "unknown" ad-clipped status, were sampled and heads collected for CWT recovery. Bio-sampling data from CFH used as a surrogate. | CDFW |
| Butte Creek Spring and Fall | Superpopulation modification of the Cormack-Jolly-Seber mark-recapture estimate for spring-run and fall-run. All fish examined for fin-clips, tags, marks. Systematic random bio-sample of all fish. No ad-clipped fish were observed in either survey. Grilse cutoff: 600 mm spring, 650 mm fall. | CDFW |

Table 1b. Estimation and sampling methods used for the 2019 CV Chinook natural escapement. (Page 2 of 2)

| Sampling Location | Estimation and Sampling Methods | Agency |
| :---: | :---: | :---: |
| Natural Spawners cont. |  |  |
| Feather River Fall | Superpopulation modification of the Cormack-Jolly-Seber mark-recapture estimate. All fish examined for fin-clips, tags, marks. Systematic random bio-sample of fresh fish. All ad-clipped fresh fish sampled and heads collected for CWT recovery. Escapement estimate includes spring-run. Grilse cutoff: 650 mm . | DWR |
| Yuba River Fall | Above Daguerre Point Dam (DPD): Vaki Riverwatcher direct count of escapement and ad-clipped fish. Supplemental carcass survey to collect bio-data and heads from ad-clipped fish (fresh fish only). Below DPD: Superpopulation modification of the Cormack-Jolly-Seber mark-recapture estimate. All fish examined for fin-clips, tags, marks, and condition. All ad-clipped fresh fish sampled and heads collected for CWT recovery. Escapement estimate includes spring-run. Grilse cutoff: 650 mm . | CDFW, <br> YARMT |
| American River Fall | Superpopulation modification of the Cormack-Jolly-Seber mark-recapture estimate, including all fish trapped between Nimbus Dam and the Nimbus Fish Hatchery weir, and all dead fish ("washbacks") that were sampled on the weir. All fish examined for fin-clips, tags, marks, and condition. Systematic random bio-sample of all fish. All ad-clipped fish sampled and heads collected for CWT recovery. Grilse cutoff: 590 mm females, 670 mm males. | CDFW |
| Mokelumne River Fall | Video count at Woodbridge Irrigation District Dam (WIDD) used to determine total escapement and ad-clipped fish above WIDD. Natural spawner escapement estimate and ad-clip rate calculated by subtracting total count and number of adclipped fish returning to MOK. Supplemental carcass survey to collect bio-data from fresh fish and heads from all ad-clipped fish. Grilse cutoff: 700 mm . | EBMUD |
| Stanislaus River Fall | Superpopulation modification of the Cormack-Jolly-Seber mark-recapture estimate. All fresh fish examined for fin-clips, tags, marks. All fresh ad-clipped fish sampled and heads collected for CWT recovery. Grilse cutoff: 610 mm females, 670 mm males. | CDFW |
| Tuolumne River Fall | Superpopulation modification of the Cormack-Jolly-Seber mark-recapture estimate. All fish examined for fin-clips, tags, marks, and condition. All ad-clipped fish sampled and heads collected for CWT recovery. Grilse cutoff: 610 mm females, 670 mm males. | CDFW |
| Merced River Fall | Superpopulation modification of the Cormack-Jolly-Seber mark-recapture estimate. All fresh fish examined for fin-clips, tags, marks. All fresh ad-clipped fish sampled and heads collected for CWT recovery. Grilse cutoff: 610 mm females, 670 mm males. | CDFW |
| Upper San Joaquin River Mainstem Spring | Direct count of carcasses encountered in the upper San Joaquin Restoration Area. All fish examined for fin-clips, tags, marks, condition, and other bio-data. Heads collected for CWT recovery from all fish regardless of ad-clip status. Using various tags and later confirmed with CWTs, all fish classified as either: 1) volitional returns via the Eastside Bypass, 2) translocated from downstream traps, or 3) captive broodstock adult releases. Fish determined to be captive broodstock are removed from the escapement estimate. Fish found dead in downstream traps are biosampled in the same manner as other carcasses and are added to the escapement estimate. | FWS, CDFW |

[^1]Table 1c. Survey design and open dates for the 2019 CV Chinook river sport harvest.

| Sampling Location | Survey Design and Open Dates | Agency |
| :--- | :--- | :--- |
| Sport Harvest | Survey Design |  |
| Central Valley Angler | Stratified-random sampling design (four weekday and four weekend samples per month <br> per section during the open season in each management zone) that included roving <br> counts, roving interviews, access interviews, and sub-sampling of kept salmon. <br> Survey (CVAS) | CDFW |
|  | Almost all ad-clipped salmon sampled and heads collected for CWT recovery. <br> Estimates of fishing effort, catch, and harvest of Chinook salmon made monthly for <br> each survey section and then summed for the season total. Grilse cutoff for <br> Sacramento Basin fall-run fishery sectors: 689 mm females, 694 mm males. |  |

Upper Sacramento River Fall and Late-Fall

Feather River Fall

American River Fall

Lower Sacramento River Fall

Mokelumne River Fall

## Open Dates

Stratified-random sampling design (four weekday and four weekend samples per month per section during the open season in each management zone) that included roving counts, roving interviews, access interviews, and sub-sampling of kept salmon. Estimates of fishing effort, catch, and harvest of Chinook salmon made monthly for each survey section and then summed for the season total. Grilse cutoff for Sacramento Basin fall-run fishery sectors: 689 mm females, 694 mm males.

Open Aug 1 - Dec 16 from the Deschutes Road Bridge to Red Bluff Diversion Dam and Jul 16 - Dec 16 from Red Bluff Diversion Dam to the Highway 113 bridge near Knights Landing. Nov 1 is used to delineate the cutoff between the fall-run fishery and the late-fall-run fishery.

Open Jul 16 - Oct 31 from the unimproved boat ramp above the Thermalito Afterbay Outfall to 200 yards above the Live Oak boat ramp and Jul 16 - Dec 16 from 200 yards above the Live Oak boat ramp to the Sacramento River confluence.

Open Jul 16 - Oct 31 from the USGS cable crossing to the SMUD power line crossing, Jul 16 - Dec 31 from the SMUD power line crossing to the Jibboom Street Bridge, and Jul 16 - Dec 16 from the Jibboom Street Bridge to the Sacramento River confluence.

Open Jul 16 - Dec 16 from the Highway 113 bridge near Knights Landing to the Carquinez Bridge.

Open Jul 16 - Oct 15 from Camanche Dam to Elliot Road, Jul 16 - Dec 31 from the Elliot Road to Woodbridge Dam, including Lodi Lake, and Jul 16 - Dec 16 from the Lower Sacramento Road bridge to the San Joaquin River confluence.

## *CWT release types:

Sacramento River fall Chinook release types (SFC)
CFHF Coleman National Fish Hatchery fall in-basin releases
CFHFn Coleman National Fish Hatchery fall bay/delta net pen releases
FRHF Feather River Hatchery fall in-basin releases
FRHFn Feather River Hatchery fall bay/delta net pen releases
FRHFgg Feather River Hatchery fall Golden Gate releases (no net pens)
NIMF Nimbus Fish Hatchery fall in-basin releases
NIMFn Nimbus Fish Hatchery fall bay/delta net pen releases

## Other CV Chinook release types (OCV)

MOKF Mokelumne River Hatchery fall in-basin releases
MOKFn Mokelumne River Hatchery fall bay/delta net pen releases
MOKFnc Mokelumne River Hatchery fall coastal net pen releases
MOKFgg Mokelumne River Hatchery fall Golden Gate releases (no net pens)
MOKFb Mokelumne River Hatchery fall barge study releases
MERF Merced River Hatchery fall in-basin releases
MERFn Merced River Hatchery fall bay/delta net pen releases
MERFt Merced River Hatchery fall trucked releases (no net pens)
SacW Livingston Stone National Fish Hatchery winter in-basin releases
SacWbat Livingston Stone National Fish Hatchery winter Battle Creek reintroduction releases
FRHS Feather River Hatchery spring in-basin releases
SJOSx San Joaquin Salmon Conservation and Research Facility spring reintroduction releases
CFHL Coleman National Fish Hatchery late-fall in-basin releases

Table 4. Central Valley hatchery and natural area escapement estimates, sport harvest, and sample data, 2019.

a/ Number of Chinook salmon sampled and visually checked for a clipped adipose fin or electronically scanned to check for the presence of a CWT.
b/ As calculated, the value for $F_{\text {samp }}$ resulted in a hatchery contribution greater than $100 \%$, so it was adjusted downward until the hatchery contribution equaled $100 \%$.
c/ Late-fall-run hatchery returns and natural area escapement occurred during late-fall of 2019 through early 2020 (return year 2020).
d/ Carcass survey sample expansion factor based on fresh fish only and expanded to all valid CWT recoveries if collected (see Appendix 1).
e/ Battle Creek fall natural escapement estimated using video count minus fall return to Coleman National Fish Hatchery (CFH). Surrogate CWTs based on CFH hatchery proportion and CWT recoveries.
f/ Due to the low sample rate and paucity of CWTs collected, this sector has been excluded from further analyses in this report.
$\mathrm{g} /$ Natural area escapement CWTs collected on spawning grounds and expanded based on total ad-clip count observed via video weir (see Appendices 5 and 6 ).
 and one natural area escapement estimate is now calculated for the entire American Basin.

Table 5. Total harvest and sample data for 2019 ocean salmon sport and commercial fisheries by major port area.

| Fishery - Port Area | Ocean Harvest | Chinook Sampled ${ }^{\text {a/ }}$ | Observed Ad-Clips | Heads Processed | Valid CWTs | Sample rate (fe) | Ad-clips processed (fa) | Valid CWTs (fd) | $\begin{aligned} & \hline \text { CWT } \\ & F_{\text {samp }} \end{aligned}$ |

a/ Natural creeks can include Clear Creek, Cow Creek, Cottonwood Creek, Paynes Creek, Mill Creek, Deer Creek, and Butte Creek, depending on survey year.
b/ Ocean recoveries of SacW and SacWbat are considered one year older than those of the same brood year recovered in the CV (i.e., brood year $2017=$ age- 3 in the ocean).

a/ CFH and FRH releases recovered in the Upper Sacramento River and Yuba River, respectively, are considered stray recoveries in this table.
b/ Natural creeks can include Clear Creek, Cow Creek, Cottonwood Creek, Paynes Creek, Mill Creek, Deer Creek, and Butte Creek, depending on survey year.

## Sacramento River fall Chinook release types (SFC)

CFHF Coleman National Fish Hatchery fall in-basin releases
FRHF Feather River Hatchery fall in-basin releases
FRHFn Feather River Hatchery fall bay/delta net pen releases
FRHFgg Feather River Hatchery fall Golden Gate releases (no net pens)

## Other CV Chinook release types (OCV)

CFHL Coleman National Fish Hatchery late-fall in-basin releases
FRHS Feather River Hatchery spring in-basin releases

Alternative age-3 CWT recovery rate for CFH and FRH releases

Alternative age-4 CWT recovery rate for CFH and FRH releases

Appendix 3. Alternative CWT recovery rates for CFH and FRH releases by age in 2019.
